

# ***FYI* Radiology Manuscript Proofs**

## **Manuscript Proofs**

Your manuscript has been edited for RSNA style and usage, which are based on widely accepted conventions of grammar and the *American Medical Association Manual of Style*. Please read the attached copy carefully to ensure that your meaning has been retained.

## **Author Queries**

Queries are indicated in the margins and listed at the end of the page proofs. Please keep your changes to a minimum and correct only inaccurate items. Figure sizing and many layout decisions have already been made. Annotate the PDF proofs with your corrections using Acrobat comment and markup tools. *We recommend that you retain a copy of the corrected manuscript.*

## **Figures**

Check the fidelity and orientation of the figures. Check the placement of keys (arrows, letters, etc) on the illustrations; if repositioning is necessary, indicate the proper location on the figure itself. Illustrations become property of RSNA and will be stored for 2 years after publication. They will be returned only upon written request from the corresponding author.

## **Return and Publication**

Return corrected page proofs within 72 hours by uploading the proofs to **The Author Center**. Your paper cannot be published until we have received your corrections. *Do not impose any security on your document.*

## **Reprints**

Please e-mail inquiries regarding reprints to [reprints@rsna.org](mailto:reprints@rsna.org). Specify the number of copies and color choice (black & white or color).

 Anna Zavodni, MD  
 Christopher T. Sibley, MD  
 João A. C. Lima, MD  
 Songtao Liu, MD  
 David A. Bluemke, MD, PhD

## Purpose:

To develop a cardiac computed tomographic (CT) method with which to determine extracellular volume (ECV) fraction, with cardiac magnetic resonance (MR) imaging as the reference standard.

## Materials and Methods:

Study participants provided written informed consent to participate in this institutional review board–approved study. ECV was measured in healthy subjects and patients with heart failure by using cardiac CT and cardiac MR imaging. Paired Student *t* test, linear regression analysis, and Pearson correlation analysis were used to determine the relationship between cardiac CT and MR imaging ECV values and clinical parameters.

## Results:

Twenty-four subjects were studied. There was good correlation between myocardial ECV measured at cardiac MR imaging and that measured at cardiac CT ( $r = 0.82$ ,  $P < .001$ ). As expected, ECV was higher in patients with heart failure than in healthy control subjects for both cardiac CT and cardiac MR imaging ( $P = .03$ , respectively). For both cardiac MR imaging and cardiac CT, ECV was positively associated with end diastolic and end systolic volume and inversely related to ejection fraction ( $P < .05$  for all). Mean radiation dose was  $1.98 \text{ mSv} \pm 0.16$  (standard deviation) for each cardiac CT acquisition.

## Conclusion:

ECV at cardiac CT and that at cardiac MR imaging showed good correlation, suggesting the potential for myocardial tissue characterization with cardiac CT.

Proof Only

**F**ocal myocardial scar after myocardial infarction can be readily identified with cardiac magnetic resonance (MR) imaging with delayed gadolinium-enhanced techniques (1). Cardiac MR imaging has been well validated and enables quantification of myocardial scar mass in comparison with overall mass of the myocardium. Unfortunately, cardiac MR imaging is not widely available and has its own contraindications and limitations. Cardiac computed tomography (CT) is well tolerated by patients and has been validated for use in the detection of focal myocardial scar (2–6).

Diffuse interstitial myocardial fibrosis is an increasingly recognized disease process common to a variety of cardiomyopathies and heart failure. T1 mapping with contrast material-enhanced cardiac MR imaging has been developed to enable quantification of diffusely abnormal myocardial signal intensity (7–12). Myocardial extracellular volume (ECV) fraction represents the equilibrium distribution of gadolinium in the blood and myocardium and is derived from T1 measurements. ECV is increased in association with diffuse myocardial fibrosis, a hallmark of pathologic remodeling (13–15). Cardiac MR imaging T1 mapping with ECV determination has been validated in multiple conditions, including heart failure secondary to ischemic and nonischemic cardiomyopathies, aortic valve disease, and hypertrophic cardiomyopathy (7,9,12,16–19).

With the increasing use of cardiac CT and because myocardial fibrosis is central to many disease processes

involving the myocardium, we sought to develop a cardiac CT method with which to determine ECV fraction. We used cardiac MR imaging as the reference standard for comparison.

## Materials and Methods

### Study Population

This single-center study was approved by National Institutes of Health Clinical Center institutional review board. All study participants provided written informed consent and completed both cardiac CT and cardiac MR imaging studies on the same day within a 4-hour window. From August 2010 to October 2011, 28 participants were enrolled. Patients with New York Heart Association, or NYHA, grade II or greater heart failure and either left ventricular ejection fraction less than 40% or diagnosis of diastolic dysfunction and left ventricular ejection fraction greater than 50% were included, as were healthy individuals. Healthy subjects had no history of clinical cardiovascular disease. Normal left and right ventricular volumes and systolic functions were confirmed at cardiac MR imaging. All clinical examinations and laboratory tests were performed no more than 7 days before cardiac CT (Fig 1).

### Cardiac MR Imaging Protocol

Images were obtained in all study subjects with a 3-T imager (Verio; Siemens, Erlangen, Germany) with a 32-channel cardiovascular array coil (In Vivo, Orlando, Fla). An 11-heart-beat modified Look Locker sequence with inversion recovery was used for cardiac MR imaging T1 measurement, as described previously (20). Scanning parameters were as follows: repetition time msec/echo time msec/minimum inversion time msec, 1.9/1.0/110.0; inversion time increment, 80.0 msec; field of view, 290–360 mm; readout resolution, 192;

phase resolution, 75%–85%; section thickness, 8 mm; 35° flip angle; and generalized autocalibrating partially parallel acquisition factor, two. Short-axis images acquired with the modified Look Locker sequence with inversion recovery were obtained at the base, middle, and apical levels of the left ventricle.

Images for T1 measurements were obtained before and after intravenous infusion of gadopentetate dimeglumine (0.15 mmol per kilogram of body weight; Bayer Healthcare Pharmaceuticals, NJ) injected as a bolus at a rate of 2 mL/sec and followed by a 20-mL saline flush. Postcontrast examinations with the modified Look Locker sequence with inversion recovery were performed at the same positions as precontrast examinations 12 minutes after injection. ECV has been shown to be stable between 10 and 40 minutes after administration of gadopentetate dimeglumine (13). To assess left ventricular function, steady-state free precession cine MR short-axis images were acquired with a temporal resolution of 40 msec. Phase-sensitive inversion-recovery late gadolinium-enhanced MR imaging was performed 15 minutes after injection to assess for focal myocardial scar (21).

[AQ10]

## Advances in Knowledge

- We assessed myocardial fibrosis by determining the extracellular volume (ECV) with low-radiation (<2 mSv) cardiac CT.
- ECV measured with cardiac CT shows good reproducibility and correlates well ( $r = 0.82$ ) with ECV measured with T1-mapping cardiac MR imaging–determined values in both healthy subjects and patients with heart failure.

## Implication for Patient Care

- ECV measured with cardiac CT represents a new approach toward the clinical assessment of diffuse myocardial fibrosis.

**Figure 1:** Flowchart of image acquisition methods. CTA = CT angiography, MOLLI = modified Look Locker sequence with inversion recovery, LGE = late gadolinium enhancement.

[AQ23]

**Figure 2:** Cardiac MR imaging region of interest measurements obtained, A, before and, B, after gadolinium chelate administration and reformatted cardiac CT region of interest measurements obtained, C, before and, D, after administration of an iodinated contrast agent. For cardiac CT, the anterolateral myocardium was most reliably identified before administration of an iodinated contrast agent. There, a region of interest from the anterolateral myocardium was used for attenuation measurements. A focal myocardial scar was identified on delayed cardiac MR images and was not included in the region of interest. Red outline = myocardium, white circle = blood pool.

**Cardiac CT Protocol**

All study participants were examined with a 320-detector row CT scanner (Aquilion One; Toshiba Medical Systems, Tustin, Calif) after cardiac MR imaging. A precontrast calcium

score-type acquisition was performed with prospective electrocardiographic gating with a 400-msec single gantry rotation during an inspiratory breath hold that enables image acquisition in a single cardiac phase. Scanning

parameters were as follows: tube voltage, 120 kV; tube current, 300 mA; and section thickness, 3 mm (22). Coronary CT angiography was performed during intravenous infusion of 125 mL ± 24 (mean ± standard deviation) of iopamidol (Isovue 370; Bracco Diagnostics) at a rate of 4–5 mL/sec by using the following parameters: For subjects with a heart rate of less than 66 beats per minute, we used prospective electrocardiographic gating at 70%–80% of one R-R interval and x-ray exposure times ranging from 0.423 to 0.350 second. For subjects with a heart rate of at least 66 beats per minute, we used prospective electrocardiographic gating at 40%–80% of two R-R intervals and x-ray exposure times ranging from 0.714 second to 1.174 seconds. Additional parameters were as follows: tube voltage, 120 kV, tube current, 300–580 mA depending on body mass index and sex; gantry rotation speed, 0.35 second; section thickness, 0.5 mm; and scanning range, 128–160 mm. After a 10-minute delay, postcontrast cardiac CT was performed with parameters identical to those used for the precontrast calcium score scan.

**Data Analysis**

T1 maps from cardiac MR imaging data were calculated by using MRmap software (23). For extraction of myocardial T1 values, regions of interest for signal intensity measurement were drawn in the anterior and anterolateral segments of myocardial and blood pool contours by using QMass software (version 7.2; Medis, Leiden, the Netherlands) (Fig 2)

Proof Only

This will be discussed later in this article. None of the study subjects had focal late gadolinium enhancement in the region of interest. The average of two independent measurements made by the same observer was used for analysis. The reader was blinded to the findings of cardiac CT analysis. ECV fraction was calculated with the following equation:  $ECV = (\Delta R1_m / \Delta R1_b) \cdot (1 - Hct)$ , where  $R1_m$  is  $R1$  in the myocardium,  $R1_b$  is  $R1$  in the blood,  $Hct$  is the hematocrit level, and  $\Delta R1$  is the change in relaxivity. The change in relaxivity,  $(1/T1)$ , was determined with the following equation:  $(1/T1) = R1_{post} - R1_{pre}$ , where  $R1_{post}$  and  $R1_{pre}$  are  $R1$  after and before gadolinium chelate administration, respectively (24–26).

Left ventricular function and volumes were measured by using CIM 6.2 software (MRI Research Group, New Zealand) (27). Focal myocardial scar was defined by using MASS software (V2011-EXP; Leiden, the Netherlands) at a threshold of five standard deviations above the remote myocardium. Two observers (J.J.L., M.S.N.; 1 year and 7 years of cardiovascular imaging experience, respectively) evaluated the cardiac MR imaging data and were blinded to the clinical data.

Cardiac CT data were reformatted to the short-axis plane to correspond to the cardiac MR acquisition. Myocardial and blood pool attenuation values at the base, middle, and apex were measured

twice by the same observer with Vitrea Core fX v5 software (Vital Images, Minnetonka, Minn), and the average value was used for analysis. Attenuation values were measured in the anterior and anterolateral segments, just as they were for cardiac MR imaging, because these segments were most reliably seen on non-contrast cardiac CT images (Fig 2). ECV fraction was calculated with the following equation:  $ECV = (\Delta HU_m / \Delta HU_b) \cdot (1 - Hct)$ , where  $\Delta HU_m$  is the change in attenuation of the myocardium,  $\Delta HU_b$  is the change in attenuation of the blood, and  $Hct$  is the hematocrit level. The change in attenuation ( $\Delta HU$ ) was determined with the equation  $\Delta HU = HU_{post} - HU_{pre}$ , where  $HU_{post}$  and  $HU_{pre}$  are attenuation after

and before administration of iodinated contrast material, respectively. Coronary calcium score was quantified by using the Agatston method (28). Coronary calcium and CT angiographic data were analyzed by using Vitrea software, as described previously. Two observers (N.K., M.S.N.; 2 and 7 years of experience in cardiovascular imaging, respectively) evaluated the cardiac CT data and were blinded to the clinical data.

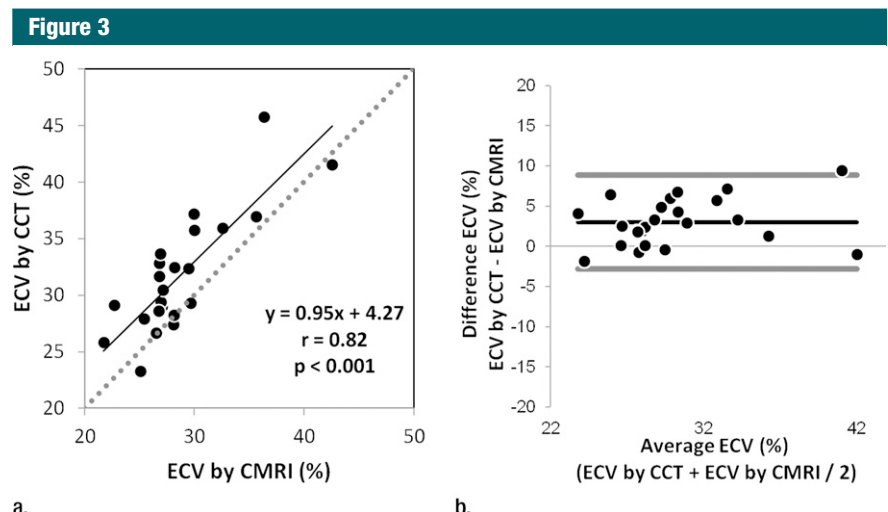

**Statistical Analysis**

The paired Student *t* test was used to determine significant differences between cardiac CT and cardiac MR imaging ECV values. Linear regression analysis and Pearson correlation were also used to examine the relationship between two methods by using ECV at cardiac MR imaging as the predictor variable and ECV at cardiac CT as the dependent variable. The Bland-Altman method was used to calculate bias and limits of agreement. Inter- and intra-observer variability were assessed with Pearson correlation as the standard deviation of the difference (SDD) between two readings. The coefficient of variation was calculated by dividing the SDD by the average of the two readings. Coronary calcium was treated as the log of the calcium score plus one. *P* < .05 was considered indicative of a significant difference.

= .23). Participant characteristics are summarized in Table 1.

Cardiac MR imaging data were available for analysis in 136 of 144 T1 maps at the base, middle, and apical levels on pre- and postcontrast images, yielding 65 of 72 ECV values with cardiac MR imaging. Seven ECV

maps could not be analyzed because of respiratory and cardiac-gating artifacts on cardiac MR images. A total of 68 of 72 ECV values were measured with cardiac CT. Four ECV maps obtained with cardiac CT were excluded because of attenuation artifacts in the area of interest.

**Figure 3:** Results obtained for ECV at (a) MR imaging and (b) CT. (a) Correlation and linear regression analysis shows good correlation between the methods (*r* = 0.82, *P* < .001). (b) Bland-Altman plot shows a small bias (3.01%) toward higher ECV at cardiac CT (black line), with a 95% limits of agreement between the two methods of -2.82 and 8.85% (thick gray lines).

[AQ19]

**Results**

The average duration of the examination was 47 minutes ± 5 for cardiac MR imaging and 13 minutes ± 1.5 for cardiac CT. Four participants were excluded: Two had atrial fibrillation, one had shortness of breath, and one had a CT protocol violation. A total of 24 participants were included for analysis; 13 subjects had heart failure, and 11 were healthy. The mean age in this population was 63.2 years ± 10 (range, 45–95 years). Male subjects had a mean age of 60.7 years ± 6.4 (range, 46–72 years), and female subjects had a mean age of 66.6 years ± 13.7 (range, 45–95 years). There was no significant difference between male and female groups in this study (*P*

**Figure 4:** Box plots show median and interquartile range. Minimum and maximum values are represented in each group by the whiskers of the plot. Healthy and heart failure groups had significantly different mean ECV values at both cardiac MR imaging and cardiac CT (*P* = .03 for both).

Note.—LV = left ventricular.

\* P values are for linear or logistic regression analysis, as appropriate, relating ECV as the dependent variable and the value in the first column as the independent variable.

† Results are from logistic regression analysis.

ECV values showed good correlation between the two methods ( $r = 0.82, P < .001$ ) (Fig 3a). ECV values were slightly lower when measured with cardiac MR imaging as opposed to cardiac CT ( $28.6\% \pm 4.4$  vs  $31.6\% \pm 5.1, P = .03$ ). The 95% limits of agreement between the two methods ranged from  $-2.82\%$  to  $8.85\%$ . A small bias (3.01%) toward higher ECV was detected for cardiac CT (Fig 3b). As expected, cardiac MR imaging-derived ECV was lower in the healthy group than in the heart failure group ( $26.6\% \pm 2.9$  vs  $30.3\% \pm 4.9$ , respectively;  $P = .03$ ). For cardiac CT, ECV was also lower for the healthy subjects than for the patients with heart failure ( $29.3\% \pm 2.7$  vs  $33.5\% \pm 5.9$ , respectively;  $P = .03$ ) (Fig 4). End-diastolic volume, end-systolic volume, and time to peak filling rate (greater time to peak filling rate indicated diastolic dysfunction) were positively associated with ECV ( $P < .001$  for all), while ejection fraction was inversely correlated with ECV for both cardiac MR imaging and cardiac CT ( $P < .05$  for all; Table 2).

The correlation coefficients for inter- and intraobserver agreement for cardiac CT were 0.95 (12.2% SDD) and 0.98 (7.5% SDD), respectively, for myocardium density measurement and 0.99 (5.1% SDD) and 0.99 (2.8% SDD), respectively, for blood pool density measurement. For cardiac MR imaging, the correlation coefficients for inter- and intraobserver agreement were 0.98 (7.9% SDD) and 0.98 (7.0% SDD), respectively, for myocardium and 0.99 (4.0% SDD) and 0.99 (2.9% SDD), respectively, for blood pool relaxivity measurements. The average radiation dose was  $1.98 \text{ mSv} \pm 0.16$  (average dose-length product,  $141.5 \text{ mGy} \cdot \text{cm} \pm 11.7$ ) for both baseline and delayed ECV measurements. The average radiation dose was  $3.14 \text{ mSv} \pm 0.82$  (average dose-length product,  $221.1 \text{ mGy} \cdot \text{cm} \pm 59.5$ ) for cardiac CT angiography.

**Discussion**

Cardiac MR imaging and cardiac CT have been used to detect areas of focal

myocardial scarring that is typically related to myocardial infarction. Recently, innovations in cardiac MR imaging technique have enabled assessment of diffuse myocardial fibrosis associated with heart failure or cardiomyopathy. By using a relatively low-radiation-dose method, ECV values for cardiac CT were shown to be comparable to those obtained with cardiac MR imaging. ECV values were elevated in subjects with heart failure; greater ECV values were associated with reduced ejection fraction and increased end-systolic and end-diastolic volumes.

ECV fraction has been shown to be a reproducible and novel index with which to assess fibrosis (11,13,24–26,29). A wide range of disease conditions, including acute and chronic myocardial infarction (30,31), chronic aortic regurgitation (32), heart failure (9), dilated cardiomyopathy (16), and hypertrophic cardiomyopathy (17) have altered ECV values at cardiac MR imaging. Iles et al (9) showed abnormal diastolic function associated with increased

collagen content. In the current study, decreased myocardial function and abnormal diastolic function were also associated with increased ECV.

There were several limitations to this study. First, we included only the anterior and anterolateral segments of the myocardium in the analysis. These regions were reliably identified on pre-contrast cardiac CT images and showed good contrast between adjacent pericardium and lung tissue. Second, cardiac CT ECV validation was based on cardiac MR imaging findings rather than on histologic specimens. Subjects in this study were not eligible for tissue biopsy. In addition, premortem human data based on tissue biopsy were limited by very small tissue specimens that were subject to sampling error. However, previous studies have shown consistent histologic correlation between cardiac MR imaging-derived T1 and ECV values in both human and animal studies (9,10,25,26). The cardiac CT method we described requires additional radiation (mean, 1.9 mSv). Lower-dose cardiac CT techniques, such as iterative image reconstruction, were not available at the time of protocol development.

In conclusion, we have described the assessment of myocardial fibrosis via ECV determination with cardiac CT. ECV measured with cardiac CT shows good reproducibility and correlates well with ECV measured with T1-mapping cardiac MR imaging-determined values, representing a potential new approach toward the clinical assessment of diffuse myocardial fibrosis.

### Author Queries

- [AQ1]: Please verify that all author names are correct and include middle initial for all authors who use one. If there is an error after the article has gone to press, we will publish an erratum, but we will be unable to fix the online version.
- [AQ2]: May we publish your e-mail address for correspondence?
- [AQ3]: Correct that you are referring to the mean  $\pm$  standard deviation?
- [AQ4]: I deleted the Experimental Studies category because I found no mention of animal studies, cadaver studies, phantom studies, or cell cultures.
- [AQ5]: Is there a grant number associated with this program? If so, please provide the grant number.
- [AQ6]: Correct that you are referring to the gadolinium itself and not a gadolinium chelate?
- [AQ7]: Correct that you are referring to the National Institutes of Health Clinical Center? If not, please provide the name of the correct institution.
- [AQ8]: Is In Vivo the name of the manufacturer or the coil?
- [AQ9]: Please include a unit of measure, if any, for readout resolution.
- [AQ10]: Please include the trade name of this contrast material, as well as the name of the city in which Bayer Healthcare Pharmaceuticals is located.
- [AQ11]: Please verify expansion of ECG as electrocardiographic.
- [AQ12]: Correct that you are referring to the mean  $\pm$  standard deviation? If not, please advise.
- [AQ13]: Please include the location of Bracco Diagnostics.
- [AQ14]: Correct that MRmap is a type of software? Please include the manufacturer name and location.
- [AQ15]: Correct that QMass is a type of software?
- [AQ16]: Please verify editing of the sentences that begin “ECV fraction...” and “The change in relaxivity...” to ensure your meaning has been retained. Please verify that all abbreviations have been expanded correctly.
- [AQ17]: Correct that CIM 6.2 is a type of software? Please include the city in which the MRI Research Group is located.
- [AQ18]: Please include an expansion for MASS. Correct that V2011-EXP is the trade name? Please include the manufacturer name.
- [AQ19]: Please clarify what is meant by the sentence “Coronary calcium was treated as log (calcium score +1).” Should this read as follows: “Coronary calcium level was the log of calcium score plus 1.”?
- [AQ20]: I deleted the Acknowledgment because this information has been included in the Funding footnote.

- 
- [AQ21]: Please include the name of the entity with which this patent is associated for M.S.N., J.Y, and D.A.B..
- [AQ22]: Reference 32 appears to be the same as reference 12. If this is indeed the case, I will delete reference 32 from the reference list and change reference 32 in the text to reference 12.
- [AQ23]: Please verify expansion of CTA, MOLLI, and LGE in the Figure 1 legend.
